1 find out what rworldmap is ?

rworldmap is an R package for visualising global scale data, concentrating on data referenced by country codes or gridded at half degree resolution. <http://cran.r-project.org/web/packages/rworldmap/index.html>

2 install rworldmap ?

To install rworldmap from R, including other required packages :
`install.packages('rworldmap',dependencies=TRUE)`

Alternatively download from :

<http://cran.r-project.org/web/packages/rworldmap/index.html>

3 load the package into R after installation ?

Package rworldmap must be loaded into R at the start of each session by either of the following 2 lines :

```
> require(rworldmap)
> library(rworldmap)
```

4 access latest version of rworldmap source code ?

<http://code.google.com/p/rworld/downloads/list>

5 access this FAQ ?

From within R :

`vignette('rworldmapFAQ')`

From the web :

<http://cran.r-project.org/web/packages/rworldmap/rworldmapFAQ.pdf>

6 map my own country level data ?

To map your own data you will need it in columns with one row per country, one column containing country identifiers, and other columns containing your data.

The mapping process then involves 3 steps (or 2 if your data are already in an R dataframe).

1. read data into R
2. join data to a map (using `joinCountryData2Map()`)
3. display the map (using `mapCountryData()`)

There is an example dataset within the package that can be accessed using the data command, and the command below shows how to display a subset of the rows and columns.

```
> data(countryExData)
> countryExData[5:10,1:5]
```

	ISO3V10	Country	EPI_regions
5	ARM	Armenia	Middle East and North Africa
6	AUS	Australia	East Asia and the Pacific
7	AUT	Austria	Europe
8	AZE	Azerbaijan	Central and Eastern Europ
9	BDI	Burundi	Sub-Saharan Africa
10	BEL	Belgium	Europe
		GEO_subregion	Population2005
5		Eastern Europe	3016.3
6	Australia + New Zealand		20155.1
7		Western Europe	8189.4
8		Eastern Europe	8410.8
9		Eastern Africa	7547.5
10		Western Europe	10419.1

6.1 Reading data into R

To read in your own data from a space or comma delimited text file you will need to use : `read.csv(filename.csv)` or `read.txt(filename.txt)`, type `?read.table` from the R console to get help on this.

6.2 Joining data to a country map

To join the data to a map use `joinCountryData2Map`, and you will need to specify the name of column containing your country identifiers (`nameJoinColumn`) and the type of code used (`joinCode`) e.g. "ISO3" for ISO 3 letter codes or "UN" for numeric country codes. If you only have country names rather than codes use `joinCode="NAME"`, you can expect more mismatches because there is greater variation in what a single country may be named.

```
> data(countryExData)
> sPDF <- joinCountryData2Map( countryExData,
+                             , joinCode = "ISO3"
+                             , nameJoinColumn = "ISO3V10" )
```

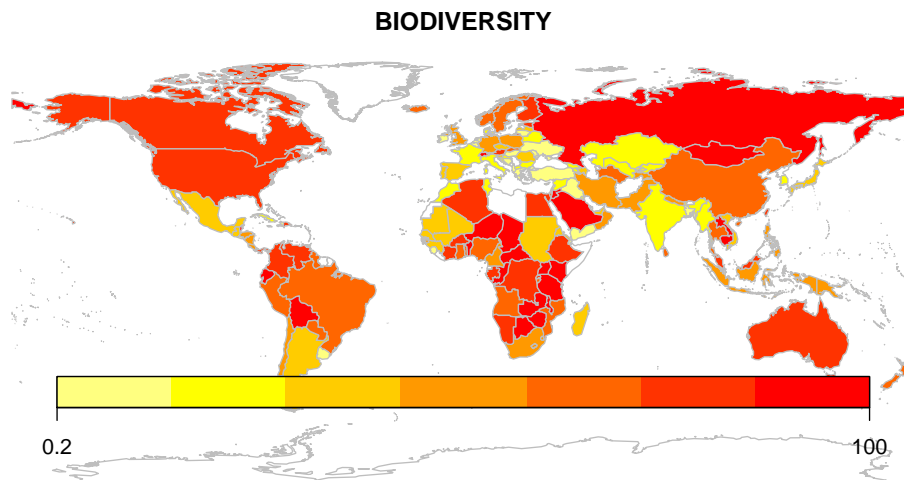

```
149 codes from your data successfully matched countries in the map
0 codes from your data failed to match with a country code in the map
97 codes from the map weren't represented in your data
```

You can see that a summary of how many countries are successfully joined is output to the console. You can specify `verbose=TRUE` to get a full list of countries. The object returned (named `sPDF` in this case) is of type `SpatialPolygonsDataFrame` from the package `sp`. This object is required for the next step, displaying the map.

6.3 Displaying a countries map

`mapCountryData` requires as a minimum a `SpatialPolygonsDataFrame` object and a specification of the name of the column containing the data to plot. The first line starting `par ...` below and in subsequent plots simply ensures the plot fills the available space on the page.

```
> par(mai=c(0,0,0.2,0),xaxs="i",yaxs="i")
> mapCountryData( sPDF, nameColumnToPlot="BIODIVERSITY" )
```

In this small map the default legend is rather large. This could be fixed by calling the `adMapLegend` function as in the code below.

```
> mapParams <- mapCountryData( sPDF
+                               , nameColumnToPlot="BIODIVERSITY"
+                               , addLegend=FALSE )
> do.call( addMapLegend, c(mapParams, legendWidth=0.5, legendMar = 2))
```

Using `do.call` allows the output from `mapCountryData` to be used in `addMapLegend` to ensure the legend matches the map while also allowing easy modification of extra parameters such as `legendWidth`.

7 map my own half degree gridded data ?

The `mapGriddedData` function can accept either

1. an object of type `SpatialGridDataFrame`, as defined in the package `sp`
2. the name of an ESRI `gridAscii` file as a character string

`rworldmap` contains an example `SpatialGridDataFrame` that can be accessed and printed as shown in the code below.

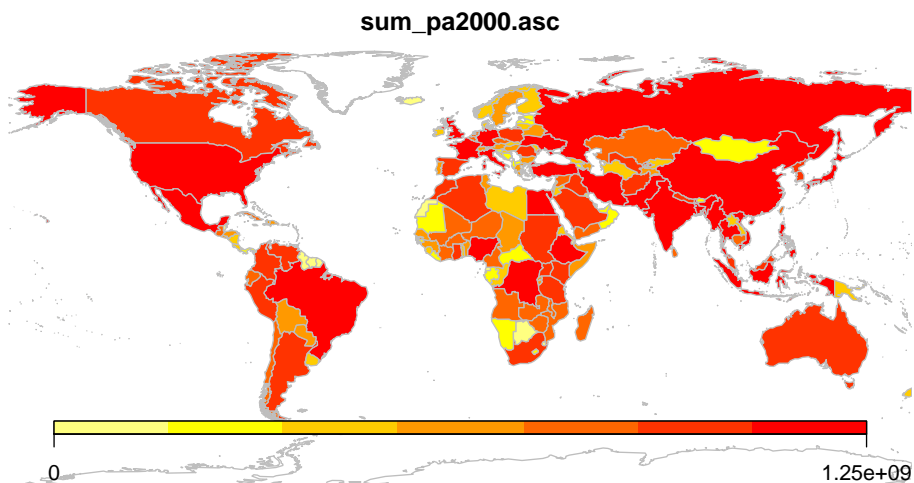

```
> par(mai=c(0,0,0.2,0),xaxs="i",yaxs="i")
> data(gridExData)
> mapGriddedData(gridExData)
```

8 aggregate half degree gridded data to countries ?

`mapHalfDegreeGridToCountries()` takes a gridded input file, and aggregates, to a country level and plots the map, it accepts most of the same arguments as `mapCountryData()`. In the example below the trick from above of modifying the legend using `addMapLegend()` is repeated.

```
> par(mai=c(0,0,0.2,0),xaxs="i",yaxs="i")
> mapParams <- mapHalfDegreeGridToCountries(gridExData, addLegend=FALSE)
> do.call( addMapLegend, c(mapParams, legendWidth=0.5, legendMar = 2))
```

9 aggregate country level data to global regions ?

Country level data can be aggregated to global regions specified by `regionType` in `country2Region` which outputs as text, and `mapByRegion` which produces a map plot. The regional classifications available include SRES, GEO3, Stern and GBD.

```
> #Using country2Region to calculate mean Environmental Health index in Stern regions.
> sternEnvHealth <- country2Region( inFile=countryExData
+                                   , nameDataColumn="ENVHEALTH"
+                                   , joinCode="ISO3"
+                                   , nameJoinColumn="ISO3V10"
```

```

+                               , regionType="Stern"
+                               , FUN="mean" )
> print(sternEnvHealth)

```

```

              meanENVHEALTHbyStern
Australasia           78.86000
Caribbean             82.18000
Central America       82.78750
Central Asia          77.24000
East Asia             75.52308
Europe                95.19762
North Africa          77.38000
North America         98.70000
South America         83.62727
South Asia            61.96000
South+E Africa        49.06316
West Africa           36.99474
West Asia             82.78000

```

```

> par(mai=c(0,0,0.2,0),xaxs="i",yaxs="i")
> mapByRegion( countryExData
+               , nameDataColumn="CLIMATE"
+               , joinCode="ISO3"
+               , nameJoinColumn="ISO3V10"
+               , regionType="Stern"
+               , FUN="mean" )

```

10 alter the appearance of my maps ?

The following arguments can be specified to alter the appearance of your plots.

- **catMethod** method for categorisation of data "pretty", "fixedWidth", "diverging", "logfixed-Width", "quantiles", "categorical", or a numeric vector defining breaks.
- **numCats** number of categories to classify the data into, may be modified if that exact number is not possible for the chosen catMethod.
- **colourPalette** a string describing the colour palette to use, choice of :

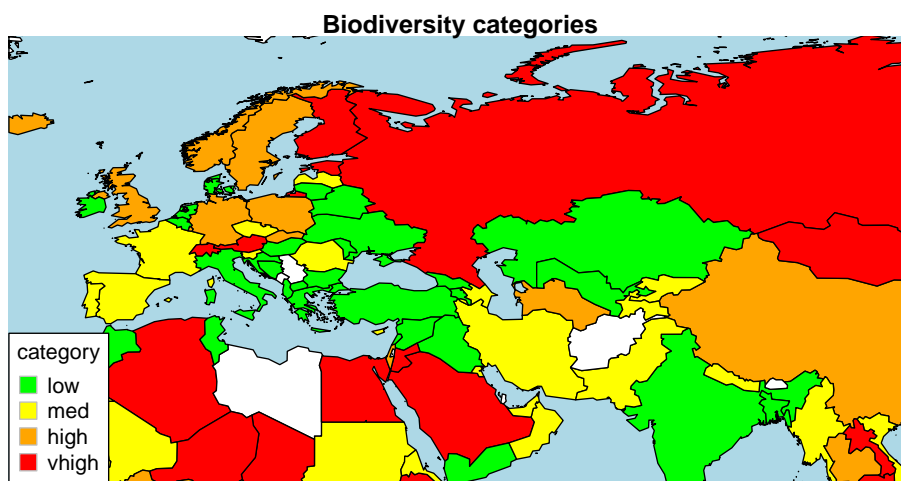

1. "palette" for the current palette
 2. a vector of valid colours, e.g. `c("red","white","blue")` or output from `RColourBrewer`
 3. one of "heat", "diverging", "white2Black", "black2White", "topo", "rainbow", "terrain", "negpos8", "negpos9"
- `addLegend` set to TRUE for a default legend, if set to FALSE the function `addMapLegend()` or `addMapLegendBoxes()` can be used to create a more flexible legend.
 - `mapRegion` a region to zoom in on, can be set to a country name from `getMap()$NAME` or one of "eurasia", "africa", "latin america", "uk", "oceania", "asia"

11 create my own colour palette ?

12 zoom in on defined regions ?

You can zoom in on a map by specifying `mapRegion="Eurasia"` (or by specifying `xlim` and `ylim`) and the country outlines can be changed by `borderCol="black"`.

```
> par(mai=c(0,0,0.2,0),xaxs="i",yaxs="i")
> mapCountryData( sPDF
+               , nameColumnToPlot='BI0categories'
+               , catMethod='categorical'
+               , mapTitle='Biodiversity categories'
+               , colourPalette='palette'
+               , oceanCol='lightblue'
+               , missingCountryCol='white'
+               , mapRegion='Eurasia'
+               , borderCol='black' )
> ## At end of plotting, reset palette to previous settings:
> palette(op)
>
```

13 create map bubble plots ?

The `mapBubbles` function allows flexible creation of bubble plots on global maps. You can specify data columns that will determine the sizing and colouring of the bubbles (using `nameZsize` and

```

> par(mai=c(0,0,0.2,0),xaxs="i",yaxs="i")
> #joining the data to a map
> sPDF <- joinCountryData2Map( countryExData
+                             , joinCode = "ISO3"
+                             , nameJoinColumn = "ISO3V10"
+                             , projection = "none" )
> #creating a user defined colour palette
> op <- palette(c('green','yellow','orange','red'))
> #find quartile breaks
> cutVector <- quantile(sPDF@data[["BIODIVERSITY"]],na.rm=TRUE)
> #classify the data to a factor
> sPDF@data[["BIOcategories"]] <- cut( sPDF@data[["BIODIVERSITY"]]
+                                     , cutVector
+                                     , include.lowest=TRUE )
> #rename the categories
> levels(sPDF@data[["BIOcategories"]]) <- c('low', 'med', 'high', 'vhigh')
> #mapping
> mapCountryData( sPDF
+                 , nameColumnToPlot='BIOcategories'
+                 , catMethod='categorical'
+                 , mapTitle='Biodiversity categories'
+                 , colourPalette='palette'
+                 , oceanCol='lightblue'
+                 , missingCountryCol='white' )

```

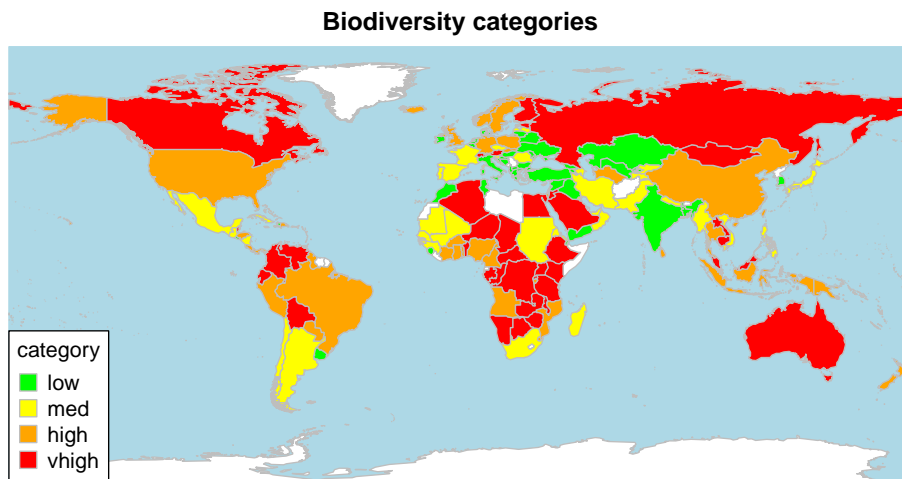

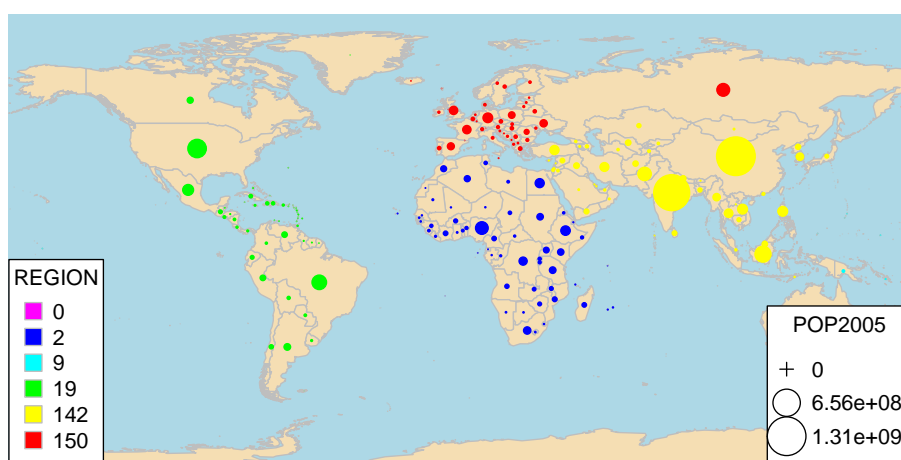

Figure 1: An example of a categorical map produced from mapCountryData

`nameZColour`). The function also accepts other `spatialDataFrame` objects or data frames as long as they contain columns specifying the x and y coordinates. The interactive function `identifyCountries` allows the user to click on bubbles and the country name and optionally an attribute variable will be printed on the map.

```
> par(mai=c(0,0,0.2,0),xaxs="i",yaxs="i")
> mapBubbles( dF=getMap()
+             , nameZSize="POP2005"
+             , nameZColour="REGION"
+             , colourPalette='rainbow'
+             , oceanCol='lightblue'
+             , landCol='wheat' )
```

14 combine `rworldmap` with other packages `classInt` and `RColorBrewer` ?

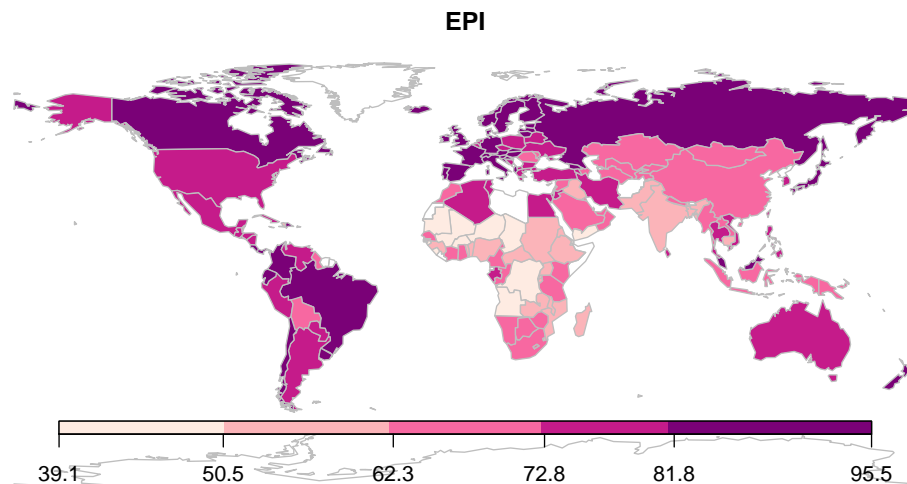

Whilst `rworldmap` sets many defaults internally there is also an option to use other packages to have greater flexibility. In this example the package `classInt` is used to create the classification and `RColorBrewer` to specify the colours. The following page demonstrates how multiple maps can be generated in the same figure and shows a selection of different `RColorBrewer` palettes.

```
> par(mai=c(0,0,0.2,0),xaxs="i",yaxs="i")
> library(classInt)
> library(RColorBrewer)
> #getting example data and joining to a map
> data("countryExData",envir=environment(),package="rworldmap")
> sPDF <- joinCountryData2Map( countryExData
+                             , joinCode = "ISO3"
+                             , nameJoinColumn = "ISO3V10"
+                             , mapResolution='coarse' )
> #getting class intervals using a 'jenks' classification in classInt package
> classInt <- classIntervals( sPDF[["EPI"]], n=5, style="jenks")
> catMethod = classInt[["brks"]]
> #getting a colour scheme from the RColorBrewer package
> colourPalette <- brewer.pal(5,'RdPu')
> #calling mapCountryData with the parameters from classInt and RColorBrewer
> mapParams <- mapCountryData( sPDF
```

```

+                                     , nameColumnToPlot="EPI"
+                                     , addLegend=FALSE
+                                     , catMethod = catMethod
+                                     , colourPalette=colourPalette )
> do.call( addMapLegend
+         , c( mapParams
+             , legendLabels="all"
+             , legendWidth=0.5
+             , legendIntervals="data"
+             , legendMar = 2 ))

```

15 ensure plots fill the panel space available?

Use `par(mar=c(bottom,top,left,right))` to set margins. This returns the previous settings so you can use `oldPar <- par(...)` then `par(oldPar)` to reset.

```

> oldPar <- par(mar=c(0, 0, 0, 0))
> par(oldPar)

```

16 create multi-panel plots ?

using the `layout()` command as shown below, `layout.show()` indicates how the panels are arranged. Beware that the colour bar legends used when `addLegend=TRUE` can interfere with this ordering (`addLegend=FALSE` or `addMapLegendBoxes()` are OK)

Creating 2 columns 5 rows with a 0.5cm gap at the top

```

> #set margins to zero for the subplots
> oldPar <- par(mar=c(0, 0, 0, 0))
> nPanels <- layout( cbind(c(0,1,2,3,4,5),c(0,6,7,8,9,10))
+                   , heights=c(1cm(0.5),1,1,1,1,1)
+                   , respect=F)
> layout.show(nPanels)
> par(oldPar)

```

1	6
2	7
3	8
4	9
5	10

Creating 3 columns 4 rows (with a gap at the top) appropriate for showing monthly data

```
> #set margins to zero for the subplots
> oldPar <- par(mar=c(0, 0, 0, 0))
> nPanels <- layout( rbind(c(0,0,0),c(1,2,3),c(4,5,6),c(7,8,9),c(10,11,12))
+                   , heights=c(1cm(0.5),1,1,1,1)
+                   , respect=F )
> layout.show(nPanels)
> par(oldPar)
```

1	2	3
4	5	6
7	8	9
10	11	12

17 add lines of latitude and longitude to a map ?

For the latitude longitude projection used in most rworldmap maps the following adds respectively
: 1) Equator 2) Greenwich meridian 3) Tropics of capricorn and cancer as dashed grey lines

```
> abline(h=0)
> abline(v=0)
> abline(h=c(-20,20),lty=2,col='grey')
```
