

Package ‘ccTensor’

August 25, 2025

Type Package

Title CUR/CX Tensor Decomposition

Version 1.0.3

Date 2025-08-25

Depends R (>= 4.1.0)

Imports methods, fields, MASS, igraph, rTensor

Suggests testthat, nnTensor

Description CUR/CX decomposition factorizes a matrix into two factor matrices and Multidimensional CX Decomposition factorizes a tensor into a core tensor and some factor matrices. See the reference section of GitHub README.md <<https://github.com/rikenbit/ccTensor>>, for details of the methods.

ccTensor-package	<i>CUR/CX Tensor Decomposition</i>
------------------	------------------------------------

Description

CUR/CX decomposition factorizes a matrix into two factor matrices and Multidimensional CX Decomposition factorizes a tensor into a core tensor and some factor matrices. See the reference section of GitHub README.md <<https://github.com/rikenbit/ccTensor>>, for details of the methods.

Details

The DESCRIPTION file:

```
Package: ccTensor
Type: Package
Title: CUR/CX Tensor Decomposition
Version: 1.0.3
Date: 2025-08-25
Authors@R: c(person("Koki", "Tsuyuzaki", role = c("aut", "cre"), email = "k.t.the-answer@hotmail.co.jp"), person("Itoshi", "Nikaido", role = "aut", email = "itoshi.nikaido@rikenbit.com"))
Depends: R (>= 4.1.0)
Imports: methods, fields, MASS, igraph, rTensor
Suggests: testthat, nmTensor
Description: CUR/CX decomposition factorizes a matrix into two factor matrices and Multidimensional CX Decomposition
License: MIT + file LICENSE

CUR

*CUR Matrix Decomposition***Description**

The input data is assumed to be a matrix. CUR decomposes the matrix to three low-dimensional factor matrices. C and R are not estimated values but the actual column and row vectors sampled from the matrix.

Usage

```
CUR(A, c.rank=NULL, r.rank=NULL, thr=0.9,
  c.method=c("best.match", "random", "exact.num.random", "top.scores"),
  u.method=c("invCR", "invW"),
  r.method=c("best.match", "random", "exact.num.random", "top.scores"))
```

Arguments

A	The input matrix which has N-rows and M-columns.
c.rank	The number of low-dimension of C ($J_1 < \{N,M\}$). If this argument is not specified or specified as NULL, the low-dimension is estimated based on the cumulative singular value (Default: NULL).
r.rank	The number of low-dimension of R ($J_2 < \{N,M\}$). If this argument is not specified or specified as NULL, the low-dimension is estimated based on the cumulative singular value (Default: NULL).
thr	The threshold to determine the low-dimension J_1 and J_2 . The value must be range 0 to 1 (Default: 0.9).
c.method	The column sampling algorithm (Default: best.match).
u.method	The algorithm to calculate U (Default: invCR).
r.method	The row sampling algorithm (Default: best.match).

Value

C: A N-rows and J_1 -columns matrix contains the sampled column vectors from the input matrix A.
U: A J_1 -rows and J_2 -columns matrix.
R: A J_2 -rows and M-columns matrix contains the sampled row vectors from the input matrix A.
indC: The sampled column indices.
indR: The sampled row indices.
RecError : The reconstruction error between data matrix and reconstructed matrix from C and X.

Examples

```
library("ccTensor")
library("nnTensor")
# Test data
matdata <- nnTensor::toyModel(model = "NMF")
# Simple usage
out <- CUR(matdata, c.rank=3, r.rank=4)
```

CX

CX Matrix Decomposition

Description

The input data is assumed to be a matrix. CX decomposes the matrix to two low-dimensional factor matrices. C is not an estimated values but the actual column vectors sampled from the matrix.

Usage

```
CX(A, rank=NULL, thr=0.9,
  c.method=c("best.match", "random", "exact.num.random", "top.scores"))
```

Arguments

A	The input matrix which has N-rows and M-columns.
rank	The number of low-dimension ($J < \{N,M\}$). If this argument is not specified or specified as NULL, the low-dimension is estimated based on the cumulative singular value (Default: NULL).
thr	The threshold to determine the low-dimension J. The value must be range 0 to 1 (Default: 0.9).
c.method	The column sampling algorithm (Default: best.match).

Value

C: A N-rows and J-columns matrix contains the sampled column vectors from the input matrix A. X: A J-rows and M-columns matrix. indC: The sampled column indices. RecError : The reconstruction error between data matrix and reconstructed matrix from C and X.

Examples

```
library("ccTensor")
library("nnTensor")
# Test data
matdata <- nnTensor::toyModel(model = "NMF")
# Simple usage
out <- CX(matdata, rank=5)
```

MultiCX

MultiCX Tensor Decomposition

Description

The input data is assumed to be a tensor. MultiCX decomposes the tensor into a core tensor and some factor matrices. The factor matrices are not estimated values but the actual column vectors sampled from the unfolded matrix in each mode.

Usage

```
MultiCX(Y, rank=NULL, modes=1:3, thr=0.9,
         c.method=c("best.match", "random", "exact.num.random", "top.scores"))
```

Arguments

Y	The input tensor (e.g. N times M times L).
rank	The number of low-dimension of factor matrices (e.g. J1, J2, and J3). If this argument is not specified or specified as NULL, the low-dimension is estimated based on the cumulative singular value (Default: NULL).
modes	The vector of the modes on whih to perform the decomposition (Default: 1:3 <all modes>).
thr	The threshold to determine the low-dimension of factor matrices. The value must be range 0 to 1 (Default: 0.9).
c.method	The column sampling algorithm (Default: best.match).

Value

U: Core tensor (e.g. J1 times J2 times J3). C: Factor matrices (e.g. C_1: ????????) RecError : The reconstruction error between data tensor and reconstructed tensor from C and X.
